ABSTRACT

Five sentences:

1) background - very specific background; hint the problem 2) problem - very very measurable problem; start with a signal word like ”However”, ”Anyhow”, ”Despite” 3) solution/what you do - Use verb wisely; explore/investigate/develop/compare 4) key findings (2-3 sentences) - summarize ONLY the key findings - it means interesting findings 5) contributions - why this is important to be solved; what impact it can bring

Exercise: within 15 mins, write down these five sentences, and then put on the chat.

NONE of you are qualified to stay away from this format. Who is qualified: very very competent writer.

Let’s analyze

Adding salt enhances the positive sensory attributes of foods (subjective).

However, consuming too much salt can raise your chances of enlarged heart muscle, headaches, heart failure, high blood pressure, kidney disease, kidney stones, osteoporosis, stomach cancer, and stroke (you write too much).

This study compared 18 flavorful salt alternatives. (but why?, where are these 18 things come from? what is the objective? no link with the problem)

The results showed that lemon juice outperformed other alternatives to brighten up the flavor of dishes (performance of what? how did you measure flavor? what does ”brighten up” mean?). Further discussion and implications were made.

This study comprehensively compares salt alternatives which can be applied to existing menus (this author does not think about real scenario....).

Let's analyze

Deep learning models are considered as blackbox and really hard to interpret (what is NOT considered as blackbox?) (when you write, NO emotion.....We never say always, never, really) (what does "interpret" mean???)

Specifically, when model makes mistakes in dialog system as model misuderstand the intent of users (huh? dialog system? it's of course.....i don't understand what you want to say)

Most model do this task are lack of interpretability (overclaim....i don't even understand what does interpretability means.....and the author even said "MOST"....).

Thus, it really is hard to track or imporve the system accordingly (until now....i still don't what the authors want to do....).

However, in dialog system, we can trace model by probing component play roles based on decisions (what does "trace" means, what does "probing" means? what does "play roles" mean? what does "decision" mean?.

The benefits of this work is to help debuging models (you never talk about debuging...).

Let's analyze

Several paradigms have been used to develop BCI Spellers to help people with neurological disorders (so i assume you will make a speller and test with people with disorders; i also assume you will develop new paradigms or new speller).

However, researchers are still working on various techniques to make the Spellers efficient (too general problem.....a good problem usually help us imagine a good

solution.....)

This paper developed a speller combining P300 potential and Steady State Visually Evoked Potential (SSVEP) paradigms, which is faster and more reliable (what does reliable means?) than the existing spellers (because your problem is not clear, i don't know whether it's a new work or not....).

We found that the hybrid speller improves the performance tremendously by improving the ITR (when you first write abbreviations, need full name) to 120 bits/min. (compare to what?)

This finding brings forward a new approach of developing of an efficient BCI Speller (what does efficient means?).

Let's analyze

Competitive online action video games have become quite popular among a large fraction of people, given its popularity, their effect on cognition have become an important topic for research (what does action mean? what does cognition mean? can be shorter....).

Despite many studies investigating the cognitive impacts of competitive online action video games (very long) exist, majority of them are cross-sectional (what does cross-sectional mean?) and lacking an active control group to compare with.

This study compares the executive cognitive functions (what are executive cognitive functions...), curiosity and aggression of a candidate online action video games (PUBG) (why PUBG????) against a brain training game (why brain training game) in a longitudinal (how long?) approach.

The study found that the cognitive effect of both of the concerned games is increasing (i still not sure how you measure....) upon the training for 2 weeks (you should put two week in the above sentence) in terms of processing speed, working

memory, task-switching ability and fluid intelligence (why these four....how about curiosity, aggression?).

contribution sentence?

Let's analyze

Diabetes is one of the highest chronic disease (but i think you can use more words to be more specific you want to do....i think is too general...i cannot imagine what you want to do).

Research found that regular self-measurement of blood glucose enhances the patient's ability to self-regulate.

but self monitor of blood sugar, especially, continuous is impossible because current feasible methods are invasion method (a little bit headache.....i still could imagine your solution).

However, existing methods are mostly invasive which do not enable continuous and easy self-measurement methods

This paper develop a mean to measure blood glucose with a non-invasive continuous method by exploiting the advancement of Raman technology (not so bad...). (he did not mention about he will find the best spot....)(he did not mention anything about ML (he did not mention what is this paradigm he will work on...) (did not mention wearable.....)

we found that the performance of nour method is not only reach the clinical level but also comparable to the old invasive fashion. the best spot to measure raman for this task is ... (secret) which out performance all previous finding in the past.

5. this research contributes in 1) best measuring spot 2) suitable ml for this task 3) exploring calibration paradigm 4) newly develop wearable device for blood

glucose monitoring. (please avoid the word ”best”....)

Let’s analyze

Question Answering (QA) systems enable users to retrieve exact answers for questions posed in natural language (you don’t need to say this....this is general knowledge). High-resource language e.g. English, Chinese etc. apporach good performance (so what? i still don’t know what you want to say....i could not imagine what would be the problem).

However, There are some gap in low-resource language (too general.....). Another challenges on thai language is how to tokenize word because this language do not have a white-space to seperate a word (there are many works - maybe 20 years already - we ALREADY know how to tokenize thai words very very well.....).

This paper explores how to improve prefomance on thai language (you should talk thai language since background....what is the problem with thai language).

Thus we will compare A,B,C which one is suitable for thai language. (why A, B, C???)(what experiments you will do)

Finally, we found that augment model with XXX techinque with A tokenizer can achive better perfomance.

Let’s analyze

Large pretrained transformer models using self-supervised learning such as BERT has attracted a lot of researchers (not so bad....maybe ok...but you can punch more if you are more specific...).

However, for low-resource language like Nepali, due to its fairly complex linguistic structures (no....you are subjective...), several feature extraction and preprocessing needs to be considered (many works already been done?) while training

traditional machine learning and deep learning models, but it lacks tools like a generic stemmer or a list of proper stop words (this problem does not sound challenging or interesting....).

no link between your problem and solution

This paper compares Nepali pre-trained language models with multilingual variants (why multilingual variants?) such as mBERT and xlm-RoBERTa models (why mBERT? why xlm-RoBERTa) with a very minimal pre-processing steps (i don't know what is your contribution....) and evaluate them to a Nepali text classification task.

Results show that, transformer models outperform traditional machine learning techniques by significant margin when given adequate amount of data. (not interesting findings.....)

This research contributes in 1) Creation of a well-balanced text classification dataset for Nepali language with more data. 2) Finding the better model by fine-tuning Nepali transformers models on text classification tasks

Exercise: Read this abstract quickly. Try to identify what is 1) background, 2) problem, 3) solution, 4) results, 5) contributions - 15 mins....

Keywords: keyword1, keyword2.

CHAPTER 1

INTRODUCTION

1.1 Background

In computer vision, self-distillation (Furlanello et al., 2018; Zhang et al., 2019; Xie et al., 2020) is a technique for improving deep learning models without increasing model size. This paradigm involves training a student model whose parameter size is equal to the teacher model with new parameter initialization. One method from this paradigm can work without any label called Self-**di**stillation with **no** labels (DINO) (Caron et al., 2021). The method has been shown to improve the performance of both ResNet (He et al., 2016) and Vision Transformers (ViT) (Dosovitskiy et al., 2021). According to Allen-Zhu and Li (2023), when using the self-distillation technique, the student model is forced to learn soft-label features, which were extracted from the dataset. Additionally, by training the model with difference parameter initialization, the student model acquires knowledge from multiple views of images. The result shows around 2% improvement by the self-distillation method over multiple ResNet models (Zagoruyko & Komodakis, 2016).

In another branch of research, a multimodal approach demonstrates that the model's performance can be improved when combining both image and text data into the model. Contrastive Language-Image Pre-training (CLIP) (Radford et al., 2021) and **A** **L**arge-scale **I**ma**G**e and **N**oisy-text embedding (ALIGN) (Jia et al., 2021) both achieved performance on par with fully supervised image classification across multiple benchmarks. These models are obtained by training the models with image-text pairs using the contrastive vision language pre-training method. The current state-of-the-art is **Co**ntrastive **Ca**ptioner (CoCa) (Yu et al., 2022). This approach used image-text pairs with contrastive language-image loss and image

captioning loss. Thus, it is a clear benefit of the training model in utilizing image and text information.

The result showed that by combining textual information with images, our approach improved accuracy by 3% in both ResNet (He et al., 2016) and ViT (Dosovitskiy et al., 2021) model compared to the baseline self-distillation method. The ablation study showed that the student model achieved 3% higher accuracy by providing detailed descriptions in the training process. This suggested that by using the text encodings with cross-attention, the model extracted higher semantic information and more precise image representations from the images.

To summarize our contribution. Firstly this paper investigated the effectiveness of combining text-image representation by using text as a query to emphasize image representation in the self-distillation method. Secondly, this work proposed a method to efficiently combine textual information and images for the self-distillation method. Lastly, this work also investigated the effect of prompts in our methods to create image descriptions for training.

CHAPTER 2

LITERATURE REVIEW

2.1 Vision-Language model

2.1.1 Learning Transferable Visual Models From Natural Language Supervision

Most computer vision deep learning pre-trained model are trained with specific set of class. For this reason, most computer vision deep learning models are lack of generalizability and usability. Radford et al. (2021) proposed pre-training method which utilize image and text description to train vision models called Contrastive Language-Image Pre-training (CLIP). The overall method is showed in Figure 2.1. The training dataset is gather from the internet in a form of (image, text) pairs of 400 million pairs. The model had a text encoder and an image encoder model. In (Radford et al., 2021), the image encoder models are ResNet and Vision Transformer and the text encoder model are transformer model. The model is optimized to maximize the similarity between each image text pair with non original image text pair as a negative target for contrastive training. As a result the CLIP model has generalizability tested by comparing CLIP zero-shot classification and linear probe on ResNet50 as showed in the Figure 2.2

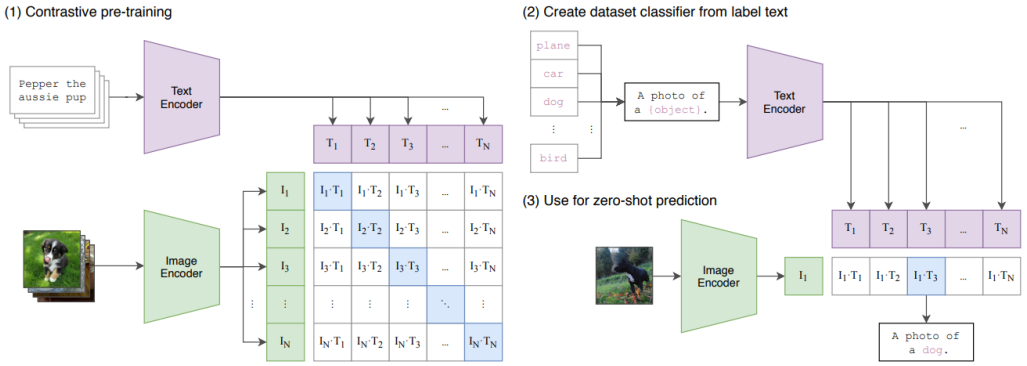
2.1.2 CoCa

2.1.3 mPlug

2.2 Knowledge Distillation and Self-Distillation

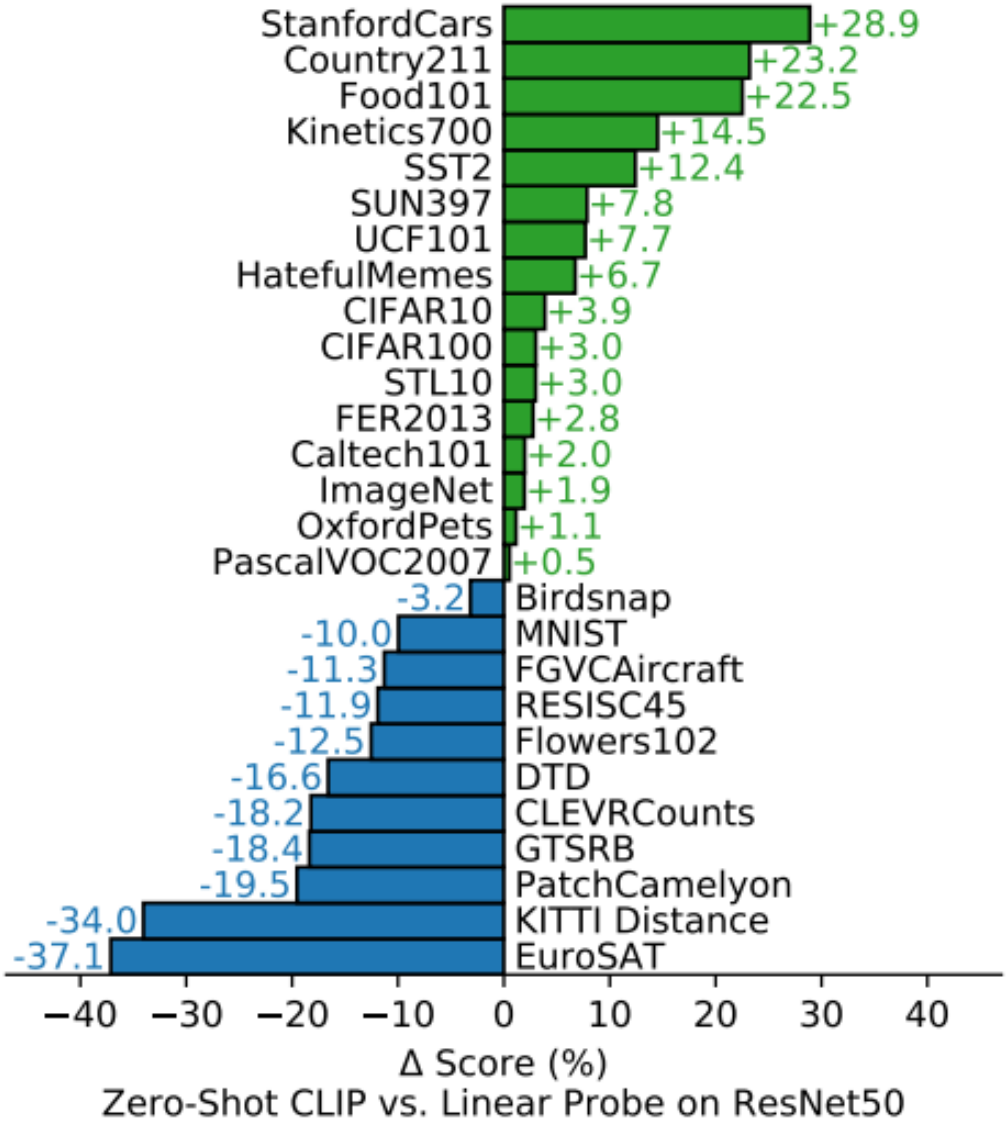
Knowledge Distillation was firstly proposed by Hinton et al. (2014) to compress the model size while maintaining the model performance as much as possible. The method contained a smaller student model and a single or multiple larger teacher model. The knowledge was transferred by optimizing the student model

Figure 2.1
Overall method of contrastive language-image pre-training



output to match the teacher's output. Furlanello et al. (2018) investigated knowledge distillation using a student model size the same as the teacher model, showing improvement in the student model. Such a method is called self-distillation. The self-distillation has widely adopted in semi-supervised image classification tasks, such as Mean Teacher (Tarvainen & Valpola, 2017), EMAN (Cai et al., 2021) and FixMatch (Sohn et al., 2020). DINO Caron et al. (2021) proposed self-distillation pre-training without using any label, which resulted in performance improvement. In this paper, we extended the self-distillation by creating representation which was image-text combined representation, and we trained the student model to match teacher softmax outputs.

Figure 2.2
Zero-shot CLIP is competitive with a fully supervised baseline.



CHAPTER 3

METHODOLOGY

The first step in the training process is to train the image-text representation head by freezing both the image and text encoder model as shown in Figure **??** a). The second step is self-distillation with combined text and image representation output from the image-text representation head as shown in Figure **??** b). Difference image and text encoder models pair are choose to demonstrate the benefit of our method. We compare our approach with other self-distillation (Furlanello et al., 2018; Xie et al., 2020). The detail of each part in this experiment is provided in this section.

3.1 Image-Text Representation Head Training

The teacher image encoder θ_{IE} and the text encoder θ_{TE} in the training are pre-trained and freezed. The image and text encoding are obtained by a mapping function $x_i' = f(x_i; \theta_{IE})$ and $t_i' = f(t_i; \theta_{TE})$ repectively. Then, the logits output from the image-text representation head transform into probability distribution output with a softmax function.

$$\hat{y}_i = \texttt{Softmax}(\texttt{Attention}(K = x_i', Q = t_i', V = x_i')) \tag{3.1}$$

The loss function for training the image-text representation head is a cross-entropy as Eq.3.2, where $y_i \in \{0,1\}^C$ is a one-hot encoded label, C is the number of target class and N is the number of training sample.

$$\mathcal{L}_{\texttt{classification}} = -\sum_{i=1}^{N} y_i \log \hat{y}_i \tag{3.2}$$

3.2 Self-Distillation

After the image-text representation head is trained, the image-text representation head is freezed during the self-distillation process. For the student model, we create a new image encoder model with same architecture as the teacher image encoder model, but with different initialized parameters. A linear classification and softmax layer is added on top of the student image encoder model to produce output distribution $\hat{s}_i$ for self-distillation process. The target for training self-distillation is the softmax output $\hat{y}_i$ from image-text representation head with the cross entropy loss as a loss function. The objective for self-distillation is cross entropy loss as showed in Eq 3.3.

$$\mathcal{L}_{\texttt{distillation}} = -\sum_{i=1}^{N} \hat{y}_i \log \hat{s}_i \tag{3.3}$$

3.3 Evaluation

In this work, we evaluate the student model with accuracy using image classification task. The benchmarks for evalutation are ImageNet, CIFAR-10 and CIFAR-100. The student model is evaluated compare to the teacher image encoder model using linear probing and student model trained with self-disillation using single image encoder as a teacher model as showed in the Table 3.1.

Table 3.1
Experiment evalutation

Teacher Image Encoder	Image Encoder Parameters	Text Encoder	Self-Distillation without Text				Self-Distillation with Text			
			CIFAR10	CIFAR100	ImageNet Top1%	ImageNet Top5%	CIFAR10	CIFAR100	ImageNet Top1%	ImageNet Top5%
ViT-B/32	86M	RoBERTa								
ViT-B/32	86M	CLIP								
ViT-B/16	86M	RoBERTa								
ViT-B/16	86M	CLIP								
ResNet-50	102M	RoBERTa								
ResNet-50	102M	CLIP								

3.4 Ablation Study

3.4.1 Few-shot learning

As this method provides texts for training student image encoder models, the texts provide additional information for better image representations. Consequently, the student model benefits from our method in few-shot learning situations. In this part, we provide benchmark results for few-shot learning situations.

3.4.2 Using Image captioning as a prompt

For better understanding the effect of text prompts in our self-distillation method, we experiment by provided better descriptive prompt. The image captioning model is used to create image description for the self-distillation process.

3.4.3 Repeatation self-distillation

By using student as a teacher model for training another student model, which have the same architecture, but with different initialized parameters. The performance increased gradually over each generation of the student model (Furlanello et al., 2018; Xie et al., 2020) In this work, we also investigate the performance increasing over each generation of the student model using our self-distillation method.

3.4.4 Image-Text Retrieval

By the increasing performance in the student model using our method with textual information, we suggest that the student would be a good image encoder which also have information about text. Such that, we can use our method to improve image-text retrieval task.
